# 1.1P: Preparing for OOP – Answer Sheet

## Introduction

This paper's answer sheet serves two purposes:

- A. It serves as a revision for you of your previous learnings; and
- B. It establishes a baseline understanding of your knowledge in key Computer Science topics.

As such this paper is divided into the following areas of knowledge:

- A. Your experience with UNIX/DOS console commands;
- B. Your ability to differentiate between data types (e.g. text) and information categories (e.g. Ktle);
- C. Your experience with compiler parsing and evaluation of expressions according to rules of precedence (e.g. BODMAS, also known as GEMS or PEMDAS);
- D. Your understanding of Computer Science concepts and various compiler constructs such as blocks and scope;
- E. Finally taking three steps, we want you to develop a program as follows:
  - 1. starting with a simple function: you provide the pure logic and calculations, no input, nor output;
  - 2. Then, in the second step, you write the main line code that invokes that simple function. Your main line code will provide the necessary data, and then you will print out the result of the function's calculation.
  - 3. Finally we want you to add business logic to the main line program's code; that business logic will interpret the results of the function, and inform your user with information about the results.

## Section A: Console commands

- 1. Explain the following terminal instructions:
  - a. `cd`: **change directory**
  - b. `pwd`: **print working directory**
  - c. `mkdir`: **make directory**
  - d. `cat`: **concatenate**
  - e. `ls`: **list**

## Section B: Data types and Information categories

1. Consider the following categories of information, and suggest the most appropriate data type to store and represent each kind of information:

| Information Category                   | Suggested Data Type |
|--|---------------------|
| A person's family name                 | String              |
| A person's age in years                | Integer             |
| A person's weight in Kilograms         | Float               |
| A telephone number                     | Long                |
| The temperature on the Kelvin scale    | Float               |
| The average age of a group of children | Float               |
| Whether the student passed this task   | Boolean             |

2. Aside from the examples already provided above, please come up with your own examples of information that could be stored as:

| Data Type | Suggested Information Category  |
|-----------|---------------------------------|
| String    | Book title, city name           |
| Integer   | Year, number of pages in a book |
| Float     | Height, price, distance         |
| Boolean   | I passed TNE                    |

## Section C: Compiler evaluation of expressions

1. Fill out the **last** two columns of the following table based on the expression and values we have supplied.
2. Evaluate the value of each expression under column 1, given its formula, values, and variables; use the given values (column 2) of any variable(s) in the expression.
3. Identify the value of the results (column 3), and the data type the result is most likely to be (column 4) in a compiler "friendly" form (e.g. Float):

| Expression | Given | Result | Data Type |
|------------|-------|--------|-----------|
| 76         |       | 76     | integer   |

|                    |                         |                  |         |
|--------------------|-------------------------|------------------|---------|
| True               |                         | true             | boolean |
| a                  | a = 3.1415927           | 3.1415927        | double  |
| 1 + 2 * 3 + 4      |                         | 11               | integer |
| a and False        | a = True                | false            | boolean |
| a or False         | a = True                | true             | Boolean |
| a + b              | a = 1<br>b = 3          | 4                | integer |
| 3 * a              | a = 5                   | 15               | integer |
| a * 2 + b          | a = 2.5<br>b = 3        | 8.0              | float   |
| a + 2 * b          | a = 2.5<br>b = 3        | 8.5              | float   |
| (a + b) * c        | a = 2<br>b = 4<br>c = 6 | 36               | integer |
| "Fred" + " Astair" |                         | Fred Astair      | string  |
| a + " Rogers"      | a = "Ginger"            | Ginger<br>Rogers | string  |

## Section D: Compiler Constructs and CS Concepts:

1. Using some code as an example, please explain the difference between **declaring** and **initialising** a variable.

The difference between the two is **declaring** is when we set the name and the type of that variable, while **initialising** is when we assign the initial value to that variable.

*Paste your example code below:*

- **Declaring:** int number;
- **Initialising:** number = 10;

2. Explain the term **parameter**. Write some **code** that demonstrates a simple of use of a parameter. You should show a procedure or function that uses a parameter, and how you would call that procedure or function. A parameter is a variable that acts as the input value of a function or procedure that allows them to further operate with the given data.

*Paste your example code below:*

```
class Program
{
    static void Greet(string name)
    {
        Console.WriteLine("Hello, " + name + "!");
    }

    static void Main()
    {
        Greet("Alice");
        Greet("Bob");
    }
}
```

3. Using an **coding example**, describe the term **scope** as it is used in procedural programming (not in business nor project management). Make sure you explain the differences of as many kinds of scope that you can identify (at least two, and up to five).

Scope is the context within a procedure or function that determines the accessibility of that procedure/function to other parts of the program

1. Global scope: accessible from any part of the program
2. Local scope: declared within a function and can be only accessed within that function or method
3. Namespace scope: declared within a “namespace” and can be accessed by all parts of the program that are within the same namespace. This is used to manage the program more effectively

*Paste your example code below:*

```
class Program
{
    static int globalVariable = 100;

    static void Main()
    {
        int localVariable = 50;
        Console.WriteLine("Global Variable: " + globalVariable);
        Console.WriteLine("Local Variable in Main: " + localVariable);

        DisplayValues();
    }
}
```

## Section E: Implementing Algorithms, Data Handling, and Informing Results - Personalized Requirements

### STEP 1:

1. In a procedural style, in any language you prefer, write a function called Average, which accepts an array of integers, and returns the average of those integers.
2. **Do not use any libraries for calculating the average:** we want to see your understanding of algorithms.
3. You must demonstrate appropriate use of parameters, returning and assigning values, and the use of loop(s). **Note — just write the function at this point.** In the next step we will ask you to *invoke the function*.
4. You should **not** have a complete program, **nor** even code that outputs anything at this stage. This is a **function**; and input/output and any business logic processing is the responsibility of the (main line) calling code.

*Paste your example function code below:*

```
//1.1 OOP HOMEWORK

int[] numbers = { 1, 2, 3, 4, 5 };
float sum = 0;

for (int i = 0; i < numbers.Length; i++)
{
    sum += numbers[i];
}

float avarage = sum / numbers.Length;
Console.WriteLine(avarage);
Console.ReadKey();
```

### STEP 2:

5. Using the same preferred language, write the main line calling code you would need to (a) marshal the data, (b) invoke the function, (c) print out the result, and (d) **print out your student name and student Id**
6. We do **not** require you to provide any input processing logic; you simply have provide the inline instantiate of a collection of data values (provided below) for the function to calculate the average of that data set.
  - a. Sample data values  
2.5, -1.4, -7.2, -11.7, -13.5, -13.5, -14.9, -15.2, -14.0, -9.7, -2.6, 2.1
7. Note: your should have made **no changes** to your function.

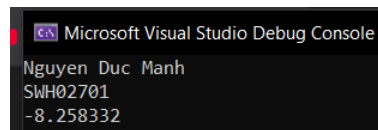

*Paste all of your example code below:*

```
//1.1 OOP HOMEWORK
double[] numbers = { 2.5, -1.4, -7.2, -11.7, -13.5,
                    -13.5, -14.9, -15.2, -14.0, -9.7, -2.6, 2.1 };
float sum = 0;

for (int i = 0; i < numbers.Length; i++)
{
    sum += (float)numbers[i];
}

float average = (float)sum / numbers.Length;
Console.WriteLine("Nguyen Duc Manh");
Console.WriteLine("SWH02701");
Console.WriteLine(average);
Console.ReadKey();
```

*Paste your example code's output here:*

```
Microsoft Visual Studio Debug Console
Nguyen Duc Manh
SWH02701
-8.258332
```

8. Using the same preferred language, add to your existing main line code above, the following business logic code for interpreting the result of the function's calculations.
9. Print the message "Multiple digits" if the average is above or equal to 10. Otherwise, print the message "Single digits".
10. And then, if the average is negative, add an additional line of output stating "Average value negative".
11. Finally, if the last digit of the average is larger than the last digit of your Student ID, please print the message "**Larger than my last digit**". Otherwise, please print the correct message, either "**Equal to my last digit**" or "**Smaller than my last digit**".
12. Note, you should not have made any changes to your implemented function
13. Provide evidence of your program running, i.e. the code, its environment, and its run time outputs.

*Paste your example code's output here:*

**Single digits**

**Average value negative**

**Larger than my last digit**

**Nguyen Duc Manh**

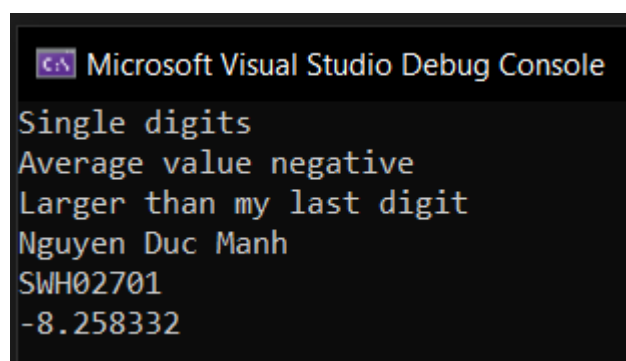

**SWH02701**

**-8.258332**

Finally on a new page paste a SINGLE screenshot of your program (main line and function) running with its outputs here:

```
//1.1 OOP HOMEWORK

double[] numbers = { 2.5, -1.4, -7.2, -11.7, -13.5,
                    -13.5, -14.9, -15.2, -14.0, -9.7, -2.6, 2.1 };
float sum = 0;
for (int i = 0; i < numbers.Length; i++)
{
    sum += (float)numbers[i];
}
float average = (float)sum / numbers.Length;
if (average >= 10)
{
    Console.WriteLine("Multiple digits");
}
else
{
    Console.WriteLine("Single digits");
}
if (average < 0)
{
    Console.WriteLine("Average value negative");
}
int studentID = 1;
int lastDigit = (int)Math.Abs(average) % 10;
if (lastDigit > studentID)
{
    Console.WriteLine("Larger than my last digit");
}
else if (lastDigit == studentID)
{
    Console.WriteLine("Equal to my last digit");
}
else
{
    Console.WriteLine("Smaller than my last digit");
}
Console.WriteLine("Nguyen Duc Manh");
Console.WriteLine("SWH02701");
Console.WriteLine(average);
Console.ReadKey();
```

Microsoft Visual Studio Debug Console

Single digits  
Average value negative  
Larger than my last digit  
Nguyen Duc Manh  
SWH02701  
-8.258332

## End of Task

Please render your paper as a PDF and submit via CANVAS.
